Abstract

The Hostel Management System (HMS) is an online solution that was created to automate and computerize the administrative processes in student hostels. It is a centralized system that ensures interaction among five diverse stakeholders, including Admin, Students, Wardens, Heads of Departments (Hods), and parents. With the help of the HMS, students can register, make out passes, monitor the status of requests, and send feedback in an electronic format. Parents can have a real-time view of the activities in their child's hostel and reply to messages from the wardens. The Admin underlies complete control with user management, which includes student, warden, and HOD records, in addition to providing analytical reports. The system was developed on the frontend interface based on HTML5, CSS 3, and JavaScript, and Python Django on the backend layer. Priority is given to security by determining the use of encryption using the Hash Algorithms Sha-256 to protect the personal information of the students and maintain confidentiality and integrity. This automated platform removes serious issues with traditional hostel management, such as manual error, sluggish approvals, communication breaches, and data security lapses. The HMS helps decrease the administrative workload, increase operational efficiency, and create more effective communication between all stakeholders by simplifying the workflow and enhancing the level of transparency. The system also provides a secure, effective, and user-friendly platform for administering a modern hostel system, which in the long term benefits students, parents, and the staff of the institution.

Graphics Abstract

1.INTRODUCTION

Education institutions across the globe must deal with the growing challenges on how to manage the hostel operations effectively and at the same time maintaining data security and stakeholder satisfaction. The Hostel Management System (HMS) is a technologically developed, multi-faceted product aimed at

converting the manual hostel administration system into a high-tech, automated, digital environment. The system provides essential solutions to the sensitive issue of centralized control over various hostel operations, such as student enrolments, out passes, feedback, and multi-stakeholder communications. The development of this system is a result of the continued inefficiencies in the traditional methods of hostel management.

Conventional systems are highly dependent on paper records, manual approval processes, and disjointed communication paths. The result of such practices would always remain a high rate of delay in handling student requests, more human errors in data handling, and reduced transparency to the parents who want to have updates on their children. Moreover, manual systems lack strong security measures; therefore, sensitive information of students is revealed to all threats of hacking and security breaches. The HMS will also provide a paradigm shift by establishing a comprehensive digital platform employing which all the actors, including students, wardens, Hods, parents, and administrators, will be able to engage each other in a seamless manner, in real time. The convenience of online outpass applications and real-time

tracking of their status is beneficial to students. Wardens are equipped with strong instruments to monitor students' activities and stay in constant touch with parents. Arts Education Hods have an effective supervisory system by approving a digital platform. The level of transparency between the parents and real-time

2. RELATED WORK

In this study, the author will work on the design of the Hostel Management System (HMS) incorporating RFID technology and QR codes in real-time attendance tracking. It automates some of the main activities, such as registering students, assigning rooms, and out pass requests, which have a high rate of errors when done manually. The system is efficient in terms of attendance records and report generation for administrators. The data are centrally stored, hence providing a sense of security and improved monitoring of student activities.

Jain and Kumar proposed a predictive maintenance model, where machine learning models are applied to oversee the infrastructure in hostels. A system that acquires sensor data monitors equipment health (probably plumbing and electrical). It can then be used to forecast equipment failures using Random Forest and SVM models, and the knowledge obtained from this can help administrators to perform timely maintenance of equipment and avoid wasting money on repairs. This system works efficiently in both the work of the hostel facilities and the security of the infrastructure system and is a sign of the use of AI in facility management.

This paper discusses a web-based hostel management tool that was developed to computerize business processes such as student registration, room assignment, and student feedback. It also has user-friendly interfaces for both wardens and students and administrators of the institution and role-specific access. The integration of real-time communication between students and hostel authorities is one of the remarkable contributions, and this will not only increase the level of satisfaction but also improve transparency. The importance of centralized data management in alleviating errors and improving decision-making processes is also discussed in this paper. Mishra and Pandey are concentrating on the hostel visitor management enhancement by means of the face recognition and RFID technology. Their system automatically checks visitors and their movements and reports them to the warden. This paper discusses the negative aspects of conventional security checkups and highlights how AI can be used to improve the safety of hostels. Such an approach will eliminate unauthorized access, provide a good audit trail, and guide hostel managers to respond adequately to security threats.

This paper presents research on data security concerns in hostel management systems. Patel and Desai consider the vulnerabilities

access to the activities of the hostel of the child and direct communication with the wardens is unprecedented. Administrators have all-purpose user management and data-driven reporting services. The HMS technical architecture integrates the latest web technologies with efficient security protocols. The frontend was developed using HTML5, CSS3, and JavaScript to provide a user-friendly and responsive interface. It uses a backend built on the Django framework of Python, which is known to be scalable, secure, and quick to develop. The introduction of SHA-256 encryption is also critical to the integrity of the system because it ensures that sensitive data regarding students are safely stored and cannot be accessed in inappropriate manners or unauthorized access.

The project can be considered the yellow wave in the field of educational technology, as it illustrates how considerate automation is capable of meeting administrative problems in the real world, improving user experience, and maintaining high control standards. In addition to increasing operational efficiency, HMS helps create a more interrelated and open hostile environment that eventually leads to improved student welfare and institutional effectiveness.

that have generally arisen in the normal systems that have failed to adequately secure the information of the student. Their proposal includes a 3-grounded security platform with access control functions based on roles and Sha-256 encryption, which is regarded as a worthwhile assurance in the storage and communication of sensitive data. This applies to security by design and offers a framework that can be integrated into hostel management systems in the future to minimize the possibility of data theft.

The authors present a web-based hostel management application that is dedicated to the optimization of activities such as the registration of students, room assignment, and maintenance. This study is based on a modular design to make the system scalable to accommodate different hostels. The other aspect that the paper will discuss is performance assessment, where the system significantly reduces processing time and manual intervention. They noted that centralized databases are critical for enhancing the efficiency and consistency of data.

This paper focuses on a multi-hostel management system that enables the management to run multi hostel in an academic institution. This means that it will be modular, with administrators being able to control student records, room management, and facilities management logistics of all the hostels using a central dashboard. The system controls various hostel entities in a better way, the information remains consistent, and any human error is reduced. It is also being used, in particular, in institutions with very large campuses with multiple hostels, requiring an administrative system that is not elaborate.

This study investigates the opportunity to use AI and IoT technologies to structure hostel management. It is also interested in automating operations such as room reservations, outpass registration, and maintenance management. One of the capabilities mentioned in the study is the ability of the system to enhance the accuracy of the data and reduce the number of individuals required to operate manually using the linked devices to monitor the situation in real time. The artificial intelligence algorithms also offer predictive modes of application, thus enabling administrators will be most likely to utilize resources and arrangements better regarding planning maintenance. The paper is also highly intelligent, providing a ten-year solution (2020) to the automation of hostels.

The article discusses a fully automated food hosting management system that simplifies the process of ordering and billing food for both administrators and students. The system also allows students to place their orders online and monitor their attendance. It also features an automated meal-billing/feedback system with traditionally manual processes. The system will reduce manual interference, thereby allowing faster processing of the records and more accurate records. This study also discusses the future of meal notifications that should be integrated through mobile.

This paper presents a fully comprehensive hostel management program that identifies some of the key concerns in the administration of these facilities, including student management, out pass, and monitoring the facilities. The authors present a role-based system according to which all users, such as wardens, students, and administrators, are granted specific access privileges. Their findings show that automated tasks incur fewer delays, errors, waste, and operational overheads, and increase the level of transparency in decision-making processes. The system is user-friendly and is therefore easier to operate by different stakeholders.

This study concerns the security of the data of students who are under the care of the hostel and recommends the use of the hash algorithm, easily known as SHA-256, to encrypt sensitive data. This study contributes to the problem of having secured storage and communication with the aim of securing student records against cyber-attacks. This security can be proposed in hostel management software using web-based applications, as outlined in this paper.

3. PROPOSED SYSTEM

The Hostel Management System (HMS) makes many hostel activities easy and automated, reducing the reliance on human hands for hostel operations and enhancing operational efficiency. The system will begin with the enrolment of students, in which they will create accounts by providing the required personal information. Room allocation takes place after registration, and students are assigned rooms based on their preferences and availability that are shared in a central database. The system can be utilized by students to make pass requests and authorization requests to be out of the hostel. These requests are approved or disapproved by the Head of Department (HOD) or a warden,

depending on the policies of the institution. The system also informs students about their requests in real time, thereby updating them in time. The warden monitors student activities and establishes an open line of communication with the students, hence creating a check that there are no issues within the hostel operations. The system enables the admin to perform all the functions of the system, including managing the data of students, rooms, and producing reports. In addition, parents may access the system to know the performance of the child at the hostel, such as checking the attendance and conduct of the child at the hostel, thus ensuring better communication between parents and hostel authorities. The biggest problem the system has inherently integrated is the problem of security and consequently, the system has utilized the use of SHA-256 to encrypt sensitive data such as student records and out passes requests. This system also provides integrated data, and unauthorized access is not provided; hence, it is efficient and secure. The system will streamline the administration and student life in the hostel by automating administrative functions and enhancing contact with and among students. The proposed system also supports real-time data updates, automated notifications, and efficient record maintenance, reducing the chances of human error and data redundancy. Furthermore, the system improves resource utilization, saves time, and provides a user-friendly interface that can be easily accessed by all authorized users. Overall, the Hostel Management System offers a smart, secure, and efficient solution for modern hostel administration by automating routine tasks, improving communication, enhancing security, and providing better management of hostel resources and student activities. It also includes attendance management and student activity monitoring functionalities. Wardens can maintain daily attendance records, monitor student movements, track hostel discipline, and manage complaints effectively. In addition, students can submit maintenance requests, complaints, or grievances directly through the system, which improves communication between hostel residents and management authorities. The administrator module acts as the central management component of the system. The administrator has complete authority to manage student records, room details, hostel occupancy, fee management, visitor records, complaint handling, and report generation. The system is capable of generating automated reports related to attendance, room occupancy, leave requests, disciplinary records, and hostel performance statistics. These reports assist hostel authorities in making data-driven administrative decisions.

Figure 1 Project Flow

4. METHODOLOGY

Hostel Management System (HMS) is established systematically under the existing guidelines of web technologies and data security that guarantee that operations of hostels are automated. The roles are set to permit multiple roles, and they are Admin, Students, Wardens, Hods and parent which have their respective access and facilities. The system has a front-end which forms an interface friendly to all the stakeholders since it is built in HTML, CSS, and JavaScript. The back-end is constructed on Python and Django software that will guarantee scalability and security and facilitate accessibility among the front-end and back-end components. Django ORM is employed to communicate with the database and this would be easy with its assistance in managing the records of the students and assigned rooms and out passing requests. To safeguard data, the system will integrate the implementation of the use of Sha-256 in encryption of sensitive information within the system,

an information containing student data, out pass request and feedback. This would ensure that any information is stored and transmitted securely and there is no unauthorized access to the information. The system embraces a centralized database whereby all records are stored with the help of central database and data retrieval to create reports in the system becomes simple. Role-Based access control (RBAC) is installed to ensure that user has access to the features and the data only which are relevant to them and help in providing feedback and real time updates. This system will contribute to the optimal use of hostel management, reduce the workload of administration and the interaction between the parties to it. The system is also made to incorporate real time notifications to ensure that all stakeholders are updated on the primary activities in the form of out pass status, room assignments and any news regarding the hostel activities. This will provide good communication without any difficulty and obstacles that will be seen during the communication process.

Figure 2 Architecture

A. Block chain Integration

The secure data storage can be used to set the procedure of delivering the integrity, the confidentiality of the information in the transactions and availability of the data. This information is enrolled into a blockchain system, the data is the record of the transaction, which is stored at a decentralized location, which may be accessed by confirming the transaction with the blockchain the storage repository or blockchain, as it is more often referred to. Each of block and transaction had an order of record, and this was not revocable and that is the block and transaction were linked to one another using a cryptographic hash of the prior block. Such structure in this instance makes it virtually impossible to effect changes and modify the information that is stored and gives authenticity of every transaction. In the process of ensuring that information which would otherwise be used to finalize the transactions is not distorted by the persons of unauthorized access, hash (e.g. Keccak-256 or SHA-256) cryptographic functions are used. This knowledge regarding the transaction can be hashing and combining it with the blockchain and hence making it an unfalsifiable record in case it possesses one in the paper. In addition to this, sensitive information can be coded and then encoded, and only the value individuals can be able to communicate on the information on the action.

A. Keccak Algorithm

Keccak algorithm is a hash algorithm the hash-function of which is cryptographic hash (a hash-function), it is the pro-type of Sha-3 family of hash functions. The Keccak, in contrast to the classical constructions of Merkle-Damgard is a sponge-based construction, and thus, it can be safely and legally extended to hash the input data. This is achieved in two general processes of absorption and squeeze. Absorption stage entails the intake of the input bits into one of the states, which is in the form of 1600 bits. This condition is again remodelled by the combination of series of operations in the manner that Keccak-f, series of operation is transformation again in the following mode 0 (Theta), 5 (Rho), 2 (Pi), 1 (Chi) and 0 (Iota) as a combination. They are coupled operations of bits in the state therefore, they are very diffusive and as well as non-linear

operations. Once all the input is read by the algorithm, the algorithm moves onto the step of squeezing and at this point the algorithm will recall a fixed sized bit of a hash output of the internal state. The hash size can be modified to suit the need of the degree of security. Keccak is designed to resist many cryptographic attacks such as preimage resistance, collision resistance and a well thought decision in blockchains and in digital signature.

Where:

- Si means the internal state upon which the i-th block has been processed.
- Si-1 is the internal condition of absence of the i-th block.
- Pi is the i-th block of data to be inputted.
- X = XOR will be denoted by the use of $\oplus$.

A. Secure Transactions Stocking

The procedure of offering the integrity, the confidentiality of the information on the transactions and the availability of information may be configured by use of the secure data storage. This data is registered in a blockchain storage network, the data reflects the transfer record, which is stored in an unstructured repository that could be accessed by validating the transfer by the blockchain storage repository or blockchain. The block and transaction received an order of records, which was final, and that they were connected by the hash cryptographic value of the previous block. This form in this case renders it impractical to alter or adjust the information that is stored and provides genuineness of all the transactions. Cryptographic functions such as hashing (e.g. Keccak-256 or SHA-256) are also used in the guaranteeing that information which would have otherwise been utilized to make the transactions are not distorted by individuals of unauthorized access. Provided that there is stored transaction, the information on the transaction can be hashing and concatenating it with blockchain and thus making it an irrevocable and verifiable record. Along with this, the sensitive information can be encrypted then stored in the form that only the authorized people can discuss the information about the transaction. This approach provides secrecy

of data and prevents unauthorized alteration or manipulation of data and unauthorized intervention. Also, the decentralized quality of blockchain is such that there is no one point of failure, as this can counter-attack or system failures. Consequently, this

model enhances the integrity of transactions and security of transactions and also ensures that the parties can check the veracity and authenticity of the records of the transactions.

5. RESULTS

A.Home Page

Figure 3 Home Page

The "Hostel Management System" is an integrated platform designed to streamline hostel operations, enabling real-time tracking, digital out pass requests, and seamless

communication between students, parents, and hostel authorities. It features role-specific dashboards for various stakeholders, including Admin, Student, HOD, Warden, and Parent.

B.UserManagement

Figure 4 Admin dashboard

The image shows the "Manage Students" section of the Hostel Management System (HMS) admin panel, where the admin can view and manage student information, including approval status, department, and contact details. It allows for easy addition of new students and tracking of their status within the system.

C. Apply Out pass

Figure 5 Apply Out pass

The image shows the "Apply for out pass" section in the Hostel Management System (HMS), where students can request an out pass by selecting the dates, providing a reason, and following important guidelines. The interface allows students to submit their request, reset the form, or cancel the action.

D. Manage Out pass

Figure 8 Manage Out pass

The image shows the "Manage Out passes" section of the Hostel Management System (HMS), where the admin can review, approve, or reject student out pass requests. It displays the total number of requests with statuses such as Pending, Approved, and Rejected.

E. Check Out pass

Figure 9 Check Out pass

The image shows the "Check Out pass" for the Warden. It allows the warden to review and manage student out pass requests, displaying total requests, along with their approval, pending, or rejection status.

F. Parent Responses

Figure 10 Dep Parent Responses

The image shows the "Parent Responses" where the admin can view and manage responses from parents regarding student out pass requests. It displays the total number of responses, with statuses such as "Responded" and "Pending."

6. DISCUSSION

The Hostel Management System (HMS) that is presented in the current project proposes the solutions to the issue of inefficiency and difficulties associated with the traditional and manual hostel management approaches. The system provides a more efficient method of handling key processes like registering students, granting them a room and out passes, thus it saves on time as well as reduces the possibility of error. The centralized database whereby student data could be easily accessed and managed is one of the major benefits of this system that contributed towards the enhancement of decision-making and transparency. The real-time notifications are another important aspect that the system provides because both the hostel authorities and a student can be updated on vital activities, including the approval of out pass requests or room allocation change. This saves on time wasted in communication and enables prompt reaction. Furthermore, the system operates with the encryption of SHA-256 which guarantees a safe storage and inaccessibility of responsible and sensitive data, e.g., the personal information of students and out passes requests. Nevertheless, the initial implementation and training of hostel admission and students to be accustomed to the new system can become a potential challenge. Although the system should be user-friendly, a learning curve could still exist. This can be enhanced by incorporating features of mobile app support in the long run to make it easier to access and allow direct communication with all the stakeholders on what to do.

7. CONCLUSION

The Hostel Management System (HMS) to be created in this project is an efficient and automated method of facilitating the otherwise manual hostel management processes. The system promotes efficiency in operations because it incorporates major features like student registration, allocation of rooms, out pass requests and real-time communication amongst many others. The centralized database of the system also allows an easy management of the data and access to this data to limit redundancy and possible mistakes. It is also secure in that it uses

SHA-256 encryption to offer protection to sensitive information like student information and out pass information. The first advantage of this system is that it saves on the administrative overhead of having to automate the lesser processes so that the hostel staff can concentrate on other more important tasks. Communication and role-based access control (RBAC) is improved with the use of real-time notifications and will optimize the transparency of the system so that students, wardens, and parents are kept informed. The system is also designed in user-friendly manner such that, all the users irrespective of their level of expertise are able to easily use and navigate the system. However, with the merits, such a system may be successfully installed provided the staff and students of the hostels have proper training and adjustment. Additional improvements in the future may be the integration of mobile application to have a more convenient and easier access to the system, which will enhance the channels of communication and the user experience. To sum up, the Hostel Management System suggested would not only streamline the processes in the management but also create transparency, security and efficiency. It offers a scalable approach that can be replicated to other schools, which is beneficial to students, administrators, and parents because of enhanced communication and working processes.

8. FUTURE SCOPE

The Hostel Management System (HMS) that was formed in this project has equipped a sturdy ground for enhancing the efficiency and management of the hostel operations. Nevertheless, it has a lot of room to develop and enlarge its functionalities in future. The mobile app integration is one of the aspects that can be further developed. Even though the existing system can be accessed through a web browser, developing a mobile application would enable the students, wardens, and parents to get easy access to key variables through the application, mobile devices in an easy and on-the-go fashion; these include out pass requests, room assignments, and notifications. Communication would also be easier and faster conducted through a mobile app, particularly to parents who do not always have a computer at their disposal. Addition of real time analytics and reporting is another area that can be improved. More features to the system could include the administrators to create extensive reports regarding the occupancy of the hostels, information on the maintenance,

student activities among others. The management of the hostel would use such insights to make meaningful decisions using data and enhance the operations in general. Also, the system may include AI-controlled proactive capabilities of maintenance, such as predicting when a room might need repair based on the usage.

This would help to avoid significant problems and enhance the maintenance of hostel centres.
